The elevation distributions of endemic beetles, butterflies and moths, and spiders and harvestmen peaked at high elevation in the subalpine and lower alpine belt (1700 – 2000 m a.s.l.), maximum endemic species diversity for caddisflies (1000 – 1200 m), and in particular for snails, was recorded at lower elevation (400 – 500 m) .

Abstract. This chapter describes the outstanding properties of high altitude environment, with particular reference to insect life. Considerable emphasis is laid on the fundamental differences between the high altitude and lowland environments. The high altitude environment is also differentiated from the arctic environment, with which it has been compared by earlier workers.

The local diversity, in contrast, is in general high on the deep-sea floor, although the true extent of regional or global biodiversity is still unknown – Remarkable exceptions on these general trends of high local diversity and low density and biomass are ecosystems, known as hydrothermal vents , and cold seeps . These systems are largely driven by chemosynthetic derived energy, and not directly dependent on photosynthesis.
