The electromyogram (EMG), an electrical recording of electrical activity in skeletal muscle that is used for the diagnosis of neuromuscular disorders, is a random signal. Stationary random signals have statistical properties, such as a mean and variance, that remain constant over time. Conversely, nonstationary random signals have statistical properties that vary with time.

Random Signals A random signal can be any signal from a set of signals $\{x_1(t), x_2(t), x_3(t), \dots\}$. The set is the sample space $\{x_1(t), x_2(t), x_3(t), \dots\}$. The probability that will equal is: $P_x(t) = P\{x(t) = x_n(t)\}$. Mean: $\bar{x}(t) = \int_{-\infty}^{\infty} x(t) P_x(t) dx(t)$. Auto-correlation:
